SECTION 3 CIRCUIT DESCRIPTION

3-1 RECEIVER CIRCUITS

3-1-1 RF FILTER CIRCUIT (MAIN UNIT)

Received signals from the antenna connector pass through the transmit/receive switching relay (FILTER board RL17) and are then applied to the MAIN unit via J2.

The signals pass through the protection relay (RL2), 1.6 MHz cut off high-pass filter (L2–L4, C4–C8, C629) and are then applied to one of nine bandpass filters (including one low-pass filter for below 2.0 MHz). These filters are selected by the filter control signals (B0–B8) as described in the table below.

The filtered signals pass through the 30 MHz cut-off low-pass filter (L71, L72, C130–C134, C618) and are then applied to the 1st mixer circuit (Q6, Q7).

• RF FILTERS USED

Frequency (MHz)	Control signal	Entrance coil	Frequency (MHz)	Control signal	Entrance coil
0.5–1.999	B0	L49	10–13.999	B5	L28
2–2.999	B1	L8	14–17.999	B6	L33
3–4.999	B2	L13	18–23.999	B7	L38
5–6.999	B3	L18	24–29.999	B8	L43
7–9.999	B4	L23			

3-1-2 1ST MIXER AND IF CIRCUITS (MAIN UNIT)

The 1st mixer circuit converts the received signals into a fixed frequency, 69.0115 MHz 1st IF signal using the PLL output frequency. By changing the PLL frequency, only the desired frequency is picked up at the pair of crystal filters (F11a, F11b) at the next stage.

The IF amplifier (Q8) and resonator circuits are designed between the filter pair. The PLL output signal (1LO) enters the MAIN unit via J3 and is amplified at the 1st LO amplifier (Q5) and then applied to the 1st mixer (Q6, Q7)

3-1-3 2ND MIXER AND IF CIRCUITS (MAIN UNIT)

The 1st IF signal from the crystal filter (F11b) is converted again into a 9.0115 MHz 2nd IF signal at the 2nd mixer circuit (D52, L66, L67). The 60 MHz 2nd local signal (2LO) from the PLL unit enters the MAIN unit via J4 to be applied to the 2nd mixer.

The 2nd IF signal is passed through the noise blanker gate (D15, D16) and amplified at the 2nd IF amplifier (Q16) and then applied to one of the 9 MHz IF filters as described below. The passed signal is amplified at the two stage 2nd IF amplifiers (Q32, Q33) and is applied to a demodulator circuit (D39 for H3E or IC10 for J3E and others).

• 2ND IF FILTERS USED

MODE	Used filter	Control signal
J3E, R3E, FSK	F12	SEL8: low, H3E8: low
H3E	F13/F14	SEL8: low, H3E8: high
FSK narrow, A1A narrow	Optional narrow filter	SEL8: high, H3E8: low

3-1-4 NOISE BLANKER CIRCUIT (MAIN UNIT)

The noise blanker circuit cuts off the IF circuit line at the moment of receiving a pulse-type noise.

A portion of the 2nd IF signal between resonator circuits (L83, L84 after stage of the 2nd mixer, D52) is amplified at the noise amplifiers (Q9, IC8, Q11). The signal is then detected at the noise detector (D17) to convert the noise components to DC voltages.

The signals are then applied to the noise blanker switch (Q13, Q14). At the moment the detected voltage exceeds the Q13's threshold level, Q14 outputs a blanking signal to close the noise blanker gate (D15, D16) by applying reverse-biased voltage. Q15 turns the noise blanker circuit ON and OFF.

• RECEIVE FREQUENCY CONSTRUCTION

The detected voltage is also applied to the noise blanker AGC circuit (Q12, Q10) and is then fed back to the noise amplifier (IC8) as a bias voltage. The noise blanker AGC circuit prevents closure of the noise blanker gate for long periods by non-pulse-type noise. The time constant of the noise blanker AGC circuit is determined by R58 and C114.

3-1-5 DEMODULATOR CIRCUIT (MAIN UNIT)

This circuit mixes the 2nd IF and BFO signals to pick up the AF components (except H3E mode). The 2nd IF signal from the 2nd IF amplifier (Q33) is applied to the balanced mixer (IC10, pin 1). The 9.0116–9.013 MHz BFO signal from the PLL unit is also applied to IC10 (pin 10). AF signals are output from pin 6 and are then applied to the AF circuits.

3-1-6 H3E DETECTOR CIRCUIT (MAIN UNIT)

The 2nd IF signal from the 2nd IF amplifier (Q33) is applied to the AM detector circuit (D39) to be demodulated into AF signals. The detected signals are amplified at the buffer amplifier (Q45) and then applied to the AF circuits.

3-1-7 AGC CIRCUIT (MAIN UNIT)

The AGC (Automatic Gain Control) circuit reduces IF amplifier gain to prevent the receiver circuit from distorting and to keep the audio output at a constant level.

A portion of the IF signals from the 2nd IF amplifier (Q33) is detected at the AGC detector circuit (D31) and is then applied to the AGC amplifier (Q41) to control the AGC time constant line. The reference voltage of the AGC line is controlled by the "RFG" line which comes from the CPU for the RF gain setting.

When receiving a strong signal, the detected voltage increases and the voltage of the AGC line is decreased by the AGC amplifier (Q41) via the -5 V voltage line. The AGC line is used for the bias voltage of the IF amplifiers (Q8, Q16, Q32, Q33), so that these amplifiers reduce gain.

When the strong signal disappears, the AGC line voltage is released by C245/R268 and C670/R813.

The AGC switch (Q42, D38) turns the AGC circuit OFF when the AGC OFF function activates. The AGC-fast switch (Q131) sets the AGC line as fast-release during scanning and A1A mode selection.

3-1-8 S-METER CIRCUIT (MAIN UNIT)

The S-meter indicates the AGC level on the display, since the AGC level varies with the received signal strength.

The AGC bias voltage (AGC time constant line) from the AGC amplifier (Q41) is inverted and amplified at the meter amplifier (IC19b). The amplified signal is applied to the CPU via the "RSM" line.

3-1-9 AF AMPLIFIER CIRCUITS (MAIN UNIT AND LOGIC BOARD)

AF signals from the demodulator or H3E detector circuits pass through the active low-pass filter (IC20b) and squelch gate (IC12a), and are then divided into the AF amplifier circuit and AF activated squelch circuit. The divided AF signals are applied to the CTRL2 board via the buffer amplifier (IC42).

The AF signals are converted into PWM signal at the PWM modulation circuit (IC4, Q11) via the AF amplifier (CTRL2 board; IC5), and are applied to the serial interface IC (IC1). The serial interface IC outputs PWM signal to the CTRL1 board (RC-21) via a coaxial cable.

The PWM signal from the IC-M710RT is applied to the LOGIC board after being converted into an analog signal by passing through the serial interface IC (IC1) on the CTRL1 board.

The AF signals are applied to the electronic volume control (LOGIC board; IC9). The CPU (pin 39) outputs the volume control signal (1 to 5 V) according to the [VOLUME] control setting.

The AF output signals from IC9 (pin 5) are amplified at the AF power amplifier (IC8) and then applied to the internal speaker via the microphone connector (pins 3 and 4).

The speaker switch relay (RL1) is connected to the (-) terminal of the internal speaker for the [SPEAKER] switch function.

• AGC circuit

3-1-10 SQUELCH CIRCUIT (MAIN UNIT)

The transceiver has two squelch circuits, voice activated squelch for J3E/H3E and S-meter squelch for A1A/FSK/J2B.

(1) AF ACTIVATED SQUELCH

A portion of the AF signal from the active low-pass filter (IC20b) is amplified at the limiter amplifier (IC20a) and is then applied to the one-shot multi-vibrator (IC22c, IC22d). The one shot multi-vibrator functions as an F-V converter which generates a signal only when audio signals are received.

The output signals pass through the NOR gate (IC22b) and then the 3 Hz low-pass filter (IC21a) to remove the remaining noise components. The filtered signal is applied to the window comparator (IC21b). The NOR gate (IC22b) deactivates the audio activated squelch during A1A/FSK/J2B mode operation.

The comparator outputs "High" when the integrated signals exceed the reference voltage. C269, R310 and R780 are used as a time constant circuit. The resulting signal output from IC22a is inverted at Q46 and is then applied to the CPU as the "SQLS" signal. The CPU controls the squelch gate (IC12a) when the "SQLS" signal is received.

(2) S-METER SQUELCH

The S-meter signal from IC19b is applied to the squelch comparator (IC19a) to close or open the squelch circuit. The reference voltage is adjusted by R257 and then applied to the (-) terminal of the comparator (IC19a). When the S-meter signal exceeds the reference voltage, the comparator outputs "High" to the CPU via IC22a and Q46 in the same manner as the voice activated squelch circuit.

3-2 TRANSMITTER CIRCUITS

3-2-1 MICROPHONE AMPLIFIER CIRCUIT (LOGIC BOARD IN THE RC-21)

The AF signals from the [MICROPHONE] connector pass through the microphone gain controller (R81) and AF amplifier (IC12a), and are applied to the CTRL1 board. The microphone AGC circuit (D9, D10, Q13, Q14) controls the amplifier gain to prevent signal distortion.

• MODULATOR CIRCUIT

The AF signals are converted into PWM signal at the PWM modulation circuit (IC3, Q1, D1) via the AF amplifier (CTRL1 board; IC4), and are applied to the serial interface IC (IC1). The serial interface IC outputs PWM signal to the CTRL2 board (IC-M710 RT) via a coaxial cable.

The PWM signal from the RC-21 (controller) is applied to the MAIN unit after being converted into an analog signal by passing through the serial interface IC on the CTRL2 board.

The AF signals are applied to the balanced modulator (MAIN unit; IC9, pin 1) via the AF switch (IC38b).

External modulation inputs from the ACC socket or a 2-tone emergency signal from the CPU are applied to the balanced modulator directly via AF switches (IC38, IC39).

3-2-2 MODULATION CIRCUIT (MAIN UNIT)

(1) J3E AND J2B MODES

The balanced modulator is used for J3E and J2B modes to add the audio signal to the BFO frequency and outputs the IF signal while suppressing the BFO signal.

The AF signals from the microphone amplifier or external audio from the modulation terminals are applied to the balanced modulator (IC9, pin 1). The BFO signal from the PLL unit is applied to IC9 (pin 10) as a carrier signal. A double sideband signal is output from IC9 (pin 6) and is then applied to the 9 MHz filter (FI2) to create an SSB signal.

R238 adjusts the balanced level of IC9 for maximum carrier suppression. In J2B mode, the BFO frequency is shifted 1.7 kHz to set the transmit frequency the same as the displayed frequency.

The SSB signal from FI2 is amplified at the 9 MHz amplifiers (Q17-Q19) and is then applied to the mixer circuit (D52). The switching diode (D19) is turned ON when R8 voltage disappears.

(2) H3E AND R3E MODES

An SSB signal is applied to the IF amplifier (Q18) in the same manner as with J3E/J2B mode. The BFO signal from the PLL unit is amplified at the buffer amplifier (Q30) and is then applied to the IF amplifier (Q18) as a carrier signal to be added to an SSB signal. R211 and R212 adjust the carrier levels in H3E and R3E modes, respectively.

(3) A1A AND FSK MODES

The CW8 or FSK8 voltage are applied to the balanced modulator (IC9, pin 4) to upset the balance and create a carrier signal.

In A1A mode, the CW keying circuit (IC18a) controls the bias voltage of the IF amplifiers (Q18, Q19) and T/R switching diode (D19) to switch the carrier transmission.

In FSK mode, BFO frequency is shifted in the PLL unit to create the mark and space frequencies.

3-2-3 1ST MIXER CIRCUIT (MAIN UNIT)

The amplified signal from the IF amplifier (Q17) is mixed with a 60 MHz LO signal at the 1st mixer circuit (D52) to produce a 69.0115 MHz IF signal. The mixer is commonly used with the receiver 2nd mixer.

The 69.0115 MHz IF signal passes through the filter (F11b) and is then applied to the 2nd mixer circuit.

3-2-4 2ND MIXER CIRCUIT (MAIN UNIT)

The filtered signal is mixed with a PLL output frequency (1LO: 69.5155–99.0155 MHz) at the 2nd mixer circuit (Q3, Q4) to produce an RF signal which is the same frequency as the displayed one.

3-2-5 RF FILTER CIRCUIT (MAIN UNIT)

The RF signal passes through the low-pass filter (L55, L56, C89–C93, C620, C628) and is then amplified at the RF amplifier (Q2).

The amplified signal is applied to one of nine RF filters. These RF filters are commonly used with the receiver circuit which consists of eight high-pass filters and one low-pass filter. The filtered signal is amplified at the RF amplifier (Q1) and is then applied to the PA150W board via J1.

3-2-6 POWER AMPLIFIER CIRCUIT (PA150W BOARD)

This circuit provides a stable 150 W (at 13.6 V DC) of output power. The RF signal from the MAIN unit is amplified at the pre-driver (Q8), driver (Q1, Q2), and power amplifier (Q3, Q4).

The driver and power amplifiers form class AB push-pull circuits. Bias voltage to these transistors is produced by diodes (D1–D3) which have temperature junctions with the transistors.

The amplified signal is then applied to one of eight low-pass filters to suppress high harmonic components. The filtered signal passes through the power detector circuit (FILTER board; L41) and transmit/receive switching relay (FILTER board; RL17) and is then applied to the antenna connector.

• LOW-PASS FILTERS USED (FILTER BOAED)

Frequency (MHz)	Control signal	Entrance coil	Frequency (MHz)	Control signal	Entrance coil
0.5–1.999	L0	RL1	10–13.999	L5	RL11
2–2.999	L1	RL3	14–17.999	L6	RL13
3–4.999	L2	RL5	18–19.999		
5–6.999	L3	RL7	20–21.999	L7	RL15
7–9.999	L4	RL9	22–23.999		
			24–29.999		

3-2-7 ALC CIRCUIT

The transceiver has two ALC (Auto Level Control) loops for constant output power over all marine bands and for high power setting.

(1) IF ALC CIRCUIT (MAIN UNIT)

A portion of the IF signals from the IF amplifier (Q17) is applied to the IF ALC circuit. The signal is amplified at Q126 and then detected at the ALC detector (D46). The detected signal is amplified at the ALC amplifier (IC17b) and is then applied to the comparator (IC17a).

• ALC CIRCUIT

The reference voltage for the comparator is set by R184. The antenna tuning control voltage (TUN8) is also affected by the reference voltage to decrease the IF signal level.

The comparator output controls the gate bias of the IF amplifier (Q19), so that the IF signal level is determined by the reference voltage of the comparator (IC17a).

(2) RF ALC CIRCUIT (FILTER BOARD)

The RF output power level is detected at D9 of the power detector circuit (L41, D9, D10) on the FILTER board. The detected signal (“FOR” signal) is applied to the RF ALC amplifier (IC16a) in the MAIN unit.

The amplified signal enters the transmit gain controller (IC16b) which functions as an inversion amplifier. The gain controller decrease the gain of the IF amplifier (Q2) on the MAIN unit to constant output power from differential amplifier gains which are occurred by their frequency characteristics.

3-2-8 APC CIRCUIT

The APC (Auto Power Control) circuit protects the power amplifiers on the PA unit from high SWR and excessive current.

(1) SWR APC (FILTER BOARD AND MAIN UNIT)

The reflected wave signal appears and increases on the antenna connector. When the antenna is mismatched, D10 of the power detector circuit (D9, D10, L41) on the FILTER board detects the signal and applies it to the APC amplifier (Q23) on the MAIN unit. The output signal decreases the bias voltage of the RF ALC amplifier to reduce the output power.

(2) CURRENT APC (PA150W BOARD AND MAIN UNIT)

The power transistor current is detected from the different voltages between both terminals of a 0.012 Ω resistor (R26) on the PA150W board. The detected voltage is applied to the differential amplifier (IC2b). When the current of the final transistors is more than 30 A, the detected voltage is applied to the APC amplifier controller (Q111) in the MAIN unit to reduce the gate-2 voltage of the IF amplifier (Q2) and thus reduce the output power.

3-2-9 TEMPERATURE DETECTION (PA150W BOARD)

Thermal switches (S1, S2) protect the final transistors from excessive temperatures. When the temperature of the final transistor (Q4) or exceeds 50 °C (122 °F), S2 is turned ON to start the cooling fan. When the temperature of the final transistor (Q3) exceeds 110 °C (230 °F), S1 is turned ON to control the “POC2” line and sets the power to 60 W.

3-2-10 RF METER CIRCUIT (MAIN UNIT)

The output of the ALC amplifier (IC16a) is applied to the CPU (pin 31) to indicate the transmit power level on the display.

for antenna current meter indication, the “ANTC” signal from an optional AT-130E is applied to the CPU (pin 32).

• PLL CIRCUIT

3-3 PLL CIRCUIT

3-3-1 GENERAL

The PLL unit generates a 1st LO frequency (69.5115-99.0114 MHz), 2nd LO frequency (60 MHz) and a BFO frequency (9.0106–9.013 MHz) for the MAIN unit. The 1st LO PLL adopts a mixerless dual loop PLL system. The BFO uses a DDS and a 2nd LO as a fixed frequency double that the crystal oscillator.

3-3-2 1ST LO PLL (PLL UNIT)

The 1st LO PLL contains a main loop and reference loop as a dual loop system. The reference loop generates a 10.65 to 10.75 MHz frequency using a DDS circuit, and the main loop generates a 69.5115 to 99.0114 MHz frequency using the reference loop frequency.

(1) REFERENCE LOOP PLL

The oscillated signal at the reference VCO (Q5, D3) is amplified at the buffer amplifiers (Q6, Q11) and is then applied to the DDS IC (IC1, pin 46). The signal is then divided and detected on phase with the DDS generated frequency.

The detected signal output from IC1 (pin 56) is converted into a DC voltage (lock voltage) at the loop filter (R18, R19, C 44) and then fed back to the varactor diode (D3) in the VCO circuit.

(2) MAIN LOOP PLL

The oscillated signal at the main loop VCO (Q3, D4) is amplified at the buffer amplifiers (Q4, Q8) and is then applied to the PLL IC (IC5, pin 14). The signal is then divided and detected on phase with the reference loop output frequency.

The detected signal output from IC5 (pins 9, 10) is converted into a DC voltage (lock voltage) at the loop filter and then fed back to the varactor diode (D4) in the VCO circuit.

The oscillated signal is amplified at the buffer amplifiers (Q4, Q21, Q24) and then applied to the MAIN unit as a 1st LO signal.

3-3-3 2ND LO AND REFERENCE OSCILLATOR CIRCUITS

The reference oscillator (X1) generates 30.0 MHz frequency used for the both DDS ICs as a system clock and for the LO output. The oscillated signal is doubled at the driver (Q2) and picked up the 60 MHz frequency at the resonator circuit (L4, L5). The 60 MHz signal is applied to the MAIN unit as a 2nd LO signal.

3-3-4 BFO CIRCUIT

The DDS IC (IC2) generates a 10-bit digital signal using the 30 MHz system clock. The digital signal is converted to an analog wave signal at the D/A converter (R120–R139). The analog wave is passed through the low-pass filter (L37, L38, C154–C158) and is then applied to the MAIN unit as the BFO signal.
